

Differences between microgrid and distributed

What are microgrids and distributed energy resources?

Microgrids and distributed energy resources (DER) are becoming a popular, cost-effective alternative to traditional transmission and distribution investments. Microgrids are small-scale electricity systems that can operate connected to the traditional grid or independently, while DER refers to various types of energy generation and storage systems that can be distributed throughout the grid. With more energy organizations modernizing grid infrastructure, the role and importance of microgrids and DER are explored in this edition of Five in 5.

How does a microgrid function?

A microgrid functions by separating itself from the electric grid and using DERs (Distributed Energy Resources) to operate when an outage is detected on the distribution system.

What is the difference between a microgrid and a generator?

While traditional generators are connected to the high-voltage transmission grid, DER are connected to the lower-voltage distribution grid, like residences and businesses are. Microgrids are localized electric grids that can disconnect from the main grid to operate autonomously.

What are the two types of microgrids?

There are two types of microgrids: Utility-owned microgrids, in which the utility company installs Distributed Energy Resources (DERs) and has a controllable load on a specific portion of its distribution system.

What happens if a microgrid goes down?

Microgrids can provide power to important facilities and communities using their distributed generation assets when the main grid goes down. Because electrical grids are run near critical capacity, a seemingly innocuous problem in a small part of the system can lead to a domino effect that takes down an entire electrical grid.

Are microgrids a potential for a modernized electric infrastructure?
