

Generator core air outlet section

How much incoming air does a generator need?

A generator typically needs 35-40% over-sizing of the incoming air based on the internal generator inlet air temperature being ambient +20 degrees Celsius. For typical 32 degrees Celsius water, there is no de-rate for single-wall application. The generator requires this amount of air for cooling purposes. For example, for every kilowatt of loss, the required flow is 1 gallon per minute.

What type of cooling system did GE use?

This type of cooling system was GE's first proven design at gap pickup cooling. (See Figure 8.) The generator rotor and stator incorporated inlet and outlet sections along their axial lengths to achieve uniform cooling along the length of the generator field.

What happens if a generator is oversized?

For a typical 20°C rise over ambient for the internal cooling circuit, an example of internal air temperature would be 40°C ambient +30°C = 70°C. The ambient air temp remains constant, and the generator needs 35-40% over-sizing to equal an ODP (Overall Design Point). This generator has cooling water inlet and outlets (TEAWC, CACW).

How does a generator work?

A generator (such as silicon or petroleum by-products) can come from nearby operations or processes. While the inlet filters eliminate most of the contaminants from the air, the flow through the generator is so great that even a small percentage in the air stream equates to significant deposits over time.

How does a generator cooling system work?

The cooling system requires airflow supplied by a fan, which is either mechanically driven from the front of the generator's ICE or is electrically driven. Cooling systems are designed to provide adequate cooling for full load operation at a specified ambient air temperature typically between 40°C; (104°F;) and 50°C; (122°F;).

How can a generator set be simulated?

Generator sets must be properly installed to ensure that cooling air is not restricted or artificially heated by nearby heat sources or from recirculation. Fortunately, installation influences can be simulated using software called Computational Fluid Dynamics. CFD is a software tool used to predict fluid flow, including thermal influences.

Visual inspection of the stator core, rotor core and winding of large motors and generators without the need to remove the rotor. ... ABB Air Gap Inspector can be used on all large synchronous ...

Download scientific diagram | The air-core reactor with: (a) general view and (b) section view. from

publication: Vibroacoustic Models of Air-Core Reactors | The purpose of this paper is to ...

Locate air inlet, ventilation and air outlet openings in a structure so that already exhausted air will not be drawn back into the building. Louvers, screening, expanded metal and other materials used to cover air openings are a ...

Core loop: The core loop test, also called core magnetization test, consists in applying 1 Tesla or nominal flux to the stator core using a toroidal winding. Heat develops at any point where the ...

If there is no exhaust pipe to exhaust the hot air outside, the fan will disperse the hot air around, and the hot air will be short circuited back to the radiator, reducing the cooling ...

The generator rotor and stator incorporated inlet and outlet sections along their axial lengths to achieve uniform cooling along the length of the generator field. This uniform cooling eliminated ...

In the next section, we will discuss how to troubleshoot common issues with running an air conditioner off a generator. Troubleshoot Common Issues with Running an Air Conditioner off a Generator When troubleshooting common ...

The stator ventilation duct is the main path for fluid flowing to cool the stator bar and the core. Considering the complexity of the ventilation system, the investigation on the ...

structure of the ventilation system of the 150 MW air-cooled turbine generator, as shown in Fig. 2, a global ow resistance network is set up to determine the ows and pressures of the inlet and ...

Ventilation structure of air-cooled turbine generator The stator ventilation system of the 150 MW generator is designed for air intake on both sides and radial ventilation ducts with unequal ...

The generator model used in this work is axially ventilated, in the sense that the flow of cooling air is axial in the air gap and in the inter-polar space (see Figures 1 and 3). The air enters the ...

The THTR-300 core outlet temperature was 750 degrees Celsius. The thermal power of 750 MW was ... the top where it enters the core region again. II.B. Steam Generator Design The helical ...
